### Summary of theory

## Chapter 3

# Basic symbolic execution for the *SImPL* language

### 3.1 description

In this chapter we will describe the process of implementing symbolic execution for a simple imperative language called *SImPL*.

### 3.2 Introducing the *SImPL* language

*SImPL* (**S**imple **I**mpерative **P**rogramming **L**anguage) is a small imperative programming language, designed to highlight the interesting use cases of symbolic execution. The language supports only one type, namely the set integers  $\mathbb{N}$ . Furthermore we will interpret 0 as *false* and any other integer as *true*. *SImPL* supports basic variables that can be assigned the value of any expression, as well as basic branching functionality through an **If - Then - Else** statement. Furthermore it allows for looping through a **While - Do** statement.

We will describe the language formally, by the following Context Free Grammar:

$$\langle int \rangle ::= 0 \mid 1 \mid -1 \mid 2 \mid -2 \mid \dots$$

$$\langle var \rangle ::= a \mid b \mid c \mid \dots$$

$$\begin{aligned} \langle exp \rangle ::= & \langle int \rangle \\ & \mid \langle var \rangle \\ & \mid \langle exp \rangle + \langle exp \rangle \mid \langle exp \rangle - \langle exp \rangle \mid \langle exp \rangle * \langle exp \rangle \mid \langle exp \rangle / \langle exp \rangle \\ & \mid \langle exp \rangle > \langle exp \rangle \mid \langle exp \rangle == \langle exp \rangle \\ & \mid ( \langle exp \rangle ) \end{aligned}$$

$$\begin{aligned} \langle stm \rangle ::= & \langle exp \rangle \\ & \mid \langle var \rangle = \langle exp \rangle \\ & \mid \langle stm \rangle \langle stm \rangle \\ & \mid \text{if } \langle exp \rangle \text{ then } \langle stm \rangle \text{ else } \langle stm \rangle \\ & \mid \text{while } \langle exp \rangle \text{ do } \langle stm \rangle \end{aligned}$$

where  $+$ ,  $*$ ,  $-$ ,  $/$  denotes the usual arithmetic operators on integers, and  $>$ ,  $==$  denotes the comparison-operators of *greater-than* and *equal-to* respectively. When interpreting a comparison-operator we will return 0 for *false* and 1 for *true*. Note that we have defined the language such that a program is simply one or more statements, and that every statement will return some value. In the case of an assign-statement, we simply return the value of the expression on the right hand side.
